Theory of strong interactions: Quantum Chromodynamics

- Fundamental field theory in hand since the early 1970s—BUT . . .
- Quark and gluon degrees of freedom in the theory cannot be observed or manipulated directly in experiment!

Color confinement—quarks and gluons are confined to color-neutral bound states

CLAS, PRL 113, 152004 (2014)
PRL Editor's Choice Oct. 2014

C. Aidala, W&M, January 30, 2015

QCD: How far have we come?

- QCD is challenging!!
- Three-decade period after initial birth of QCD dedicated to “discovery and development”
 - Symbolic closure: Nobel prize 2004 - Gross, Politzer, Wilczek for asymptotic freedom

*Now early years of second phase:
quantitative QCD!*

Advancing into the era of quantitative QCD: Theory has been forging ahead

- In perturbative QCD, since 1990s starting to consider detailed internal *dynamics* that parts with traditional parton model ways of looking at hadrons—and perform phenomenological calculations using these new ideas/tools!

E.g.:

- Various *resummation* techniques
 - *Non-linear* evolution at small momentum fractions
 - *Spin-spin* and *spin-momentum* correlations in QCD bound states
 - Techniques to handle *target-mass* and “*higher-twist*” corrections
 - *Spatial* distributions of partons in QCD bound states
- Nonperturbative methods:
 - Lattice QCD less and less limited by computing resources—since 2010 starting to perform calculations at the physical pion mass (after 36 years!). Plus recent new ideas on how to calculate previously intractable quantities.
 - AdS/CFT “gauge-string duality” an exciting recent development as first fundamentally new handle to try to tackle QCD in decades!

Effective field theories

- QCD exhibits different behavior at different scales—effective field theories are useful approximations within these different regimes
 - Color Glass Condensate – high energies, high densities
 - Soft-Collinear Effective Theory – new insights into performing complicated perturbative calculations very quickly
 - Heavy Quark Effective Theory, Non-Relativistic QCD, . . .
 - Many effective theories for nonperturbative QCD – chiral symmetry breaking, . . .

Example: “Threshold resummation”

Extending perturbative calculations to lower energies

For observables with two different scales, sum logs of their ratio to all orders in the strong coupling constant

Next-to-leading-order in α_s + resum.

Next-to-leading-order in α_s

Almeida, Sterman, Vogelsang PRD80, 074016 (2009)

Example: Phenomenological applications of a non-linear gluon saturation regime

Fits to proton structure function data at low parton momentum fraction x .

Non-linear QCD meets data: A global analysis of lepton-proton scattering with running coupling BK evolution

Phys. Rev. D80, 034031 (2009)

Javier L. Albacete¹, Néstor Armesto², José Guilherme Milhano³ and Carlos A. Salgado²

Basic framework for non-linear QCD, in which gluon densities are so high that there's a non-negligible probability for two gluons to combine, developed ~1997-2001. But had to wait until “running coupling BK evolution” figured out in 2007 to compare directly to data!

Example: Spin-spin and spin-momentum correlations in QCD bound states

Unpolarized

$$f_1 = \text{circle with a dot}$$

Spin-spin correlations

$$g_{1L} = \text{circle with dot and right arrow} - \text{circle with dot and left arrow}$$

$$h_{1T} = \text{circle with dot and up arrow} - \text{circle with dot and down arrow}$$

$$g_{1T} = \text{circle with dot and up arrow} - \text{circle with dot and left arrow}$$

Spin-momentum correlations

$$S \cdot (p_1 \times p_2)$$

$$f_{1T}^\perp = \text{circle with dot and up arrow} - \text{circle with dot and down arrow}$$

$$h_1^\perp = \text{circle with dot and right arrow} - \text{circle with dot and left arrow}$$

$$h_{1L}^\perp = \text{circle with dot and up arrow} - \text{circle with dot and down arrow}$$

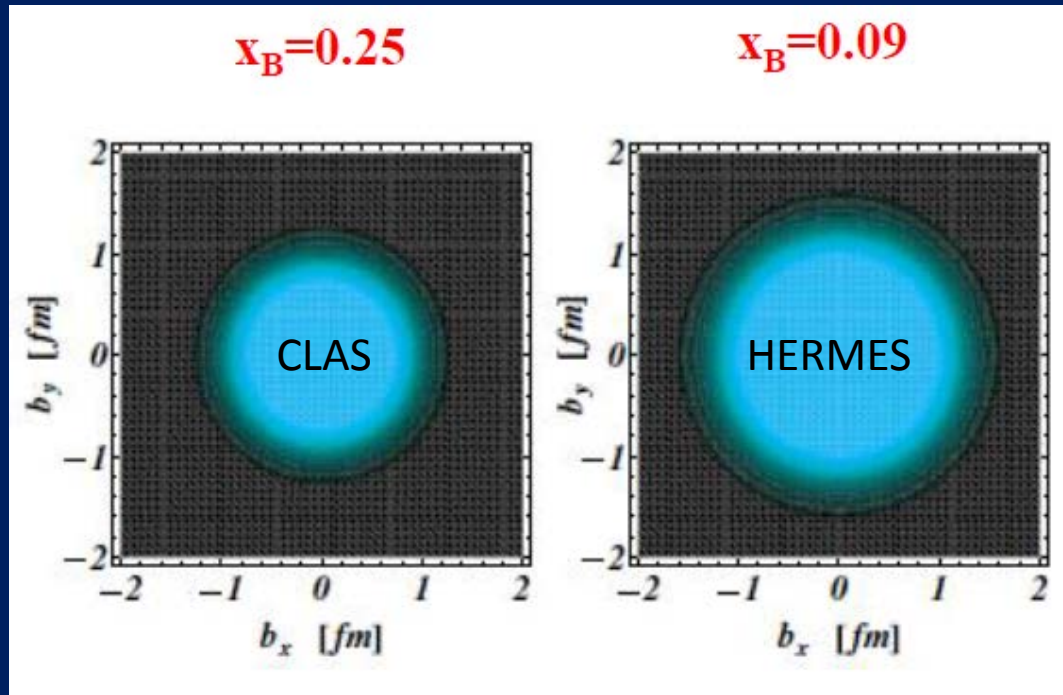

$$h_{1T}^\perp = \text{circle with dot and right arrow} - \text{circle with dot and left arrow}$$

Example: Fits to quark and gluon distributions including much wider range of data

- Incorporate corrections for target mass, “higher-twist,” and nuclear effects
- Can in turn make predictions for future measurements in extended kinematic regions

Example: Exploring spatial distributions

Spatial charge densities measured via deeply virtual Compton scattering

Guidal, Moutarde,
Vanderhaeghen,
Rept. Prog. Phys. 76 (2013) 066202

Initial evidence that quarks carrying larger momentum fractions (25% vs. 9%) in the nucleon are distributed over a smaller volume in space

Example: Progress in lattice QCD

Recent progress in LQCD suggests the possibility to calculate the x -dependence of parton distributions

Soft Collinear Effective Theory

– Transverse momentum distribution for gluon+gluon → Higgs

Mapping out the partonic structure of the proton

What does the proton look like in terms of the quarks and gluons inside it?

- *Position*
- *Momentum*
- *Spin*
- *Flavor*
- *Color*

Vast majority of past four decades focused on *1-dimensional* momentum structure! Since 1990s starting to consider transverse components . . .

Mapping out the partonic structure of the proton

What does the proton look like in terms of the quarks and gluons inside it?

- *Position*
- *Momentum*
- *Spin*
- *Flavor*
- *Color*

Polarized protons first studied in 1980s. How angular momentum of quarks and gluons add up still not well understood!

Mapping out the partonic structure of the proton

What does the proton look like in terms of the quarks and gluons inside it?

- *Position*
- *Momentum*
- *Spin*
- *Flavor*
- *Color*

Early measurements of flavor distributions in valence region. Flavor structure at lower momentum fractions still yielding surprises!

Mapping out the partonic structure of the proton

What does the proton look like in terms of the quarks and gluons inside it?

- *Position*
- *Momentum*
- *Spin*
- *Flavor*
- *Color*

Theoretical and experimental concepts to describe and access position only born in mid-1990s. Pioneering measurements over past decade.

Mapping out the partonic structure of the proton

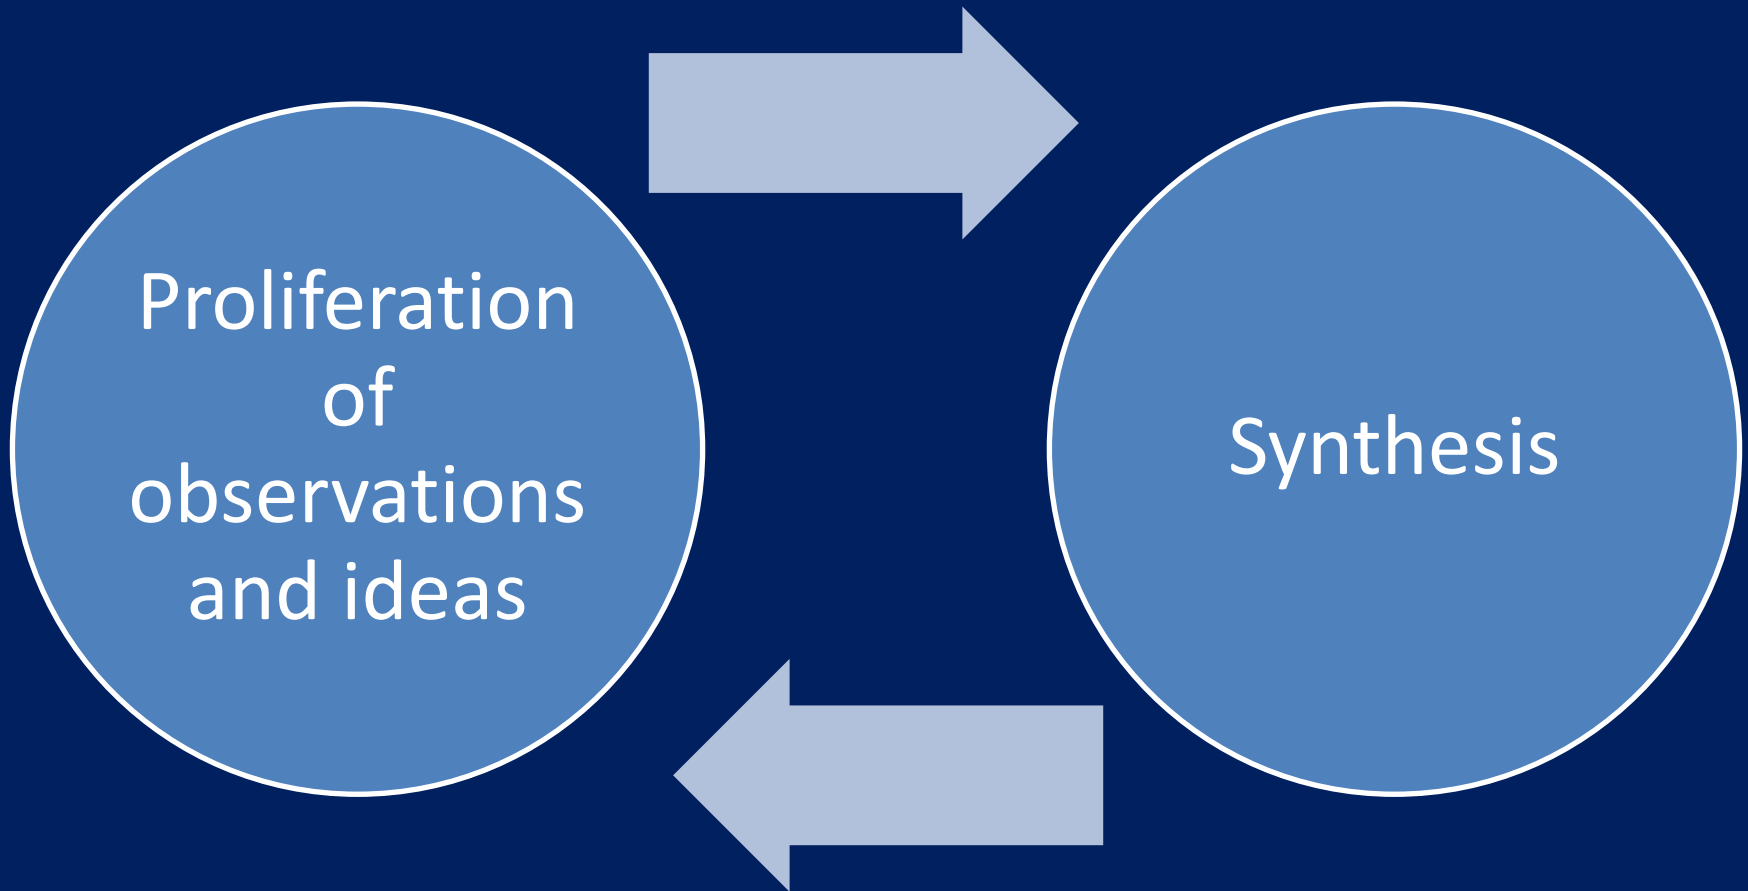

What does the proton look like in terms of the quarks and gluons inside it?

- *Position*
- *Momentum*
- *Spin*
- *Flavor*
- *Color*

Accounted for theoretically from beginning of QCD, but more detailed, potentially observable effects of color have come to forefront in last few years . . .

A cyclical process

Factorization and universality in perturbative QCD

- Need to systematically *factorize* short- and long-distance physics—observable physical QCD processes always involve at least one long-distance scale (confinement)!
- Long-distance (i.e. nonperturbative) functions need to be *universal* in order to be portable across calculations for many processes

Measure nonperturbative parton distribution functions (pdfs) and fragmentation functions in many colliding systems over a wide kinematic range → constrain by performing *simultaneous fits to world data*

Spin-momentum correlations: 1976 discovery in $p+p$ collisions

Argonne $\sqrt{s}=4.9$ GeV

W.H. Dragoset et al., PRL36, 929 (1976)

Charged pions produced preferentially on one or the other side with respect to the transversely polarized beam direction—by up to 40%!!

Had to wait more than a decade for the birth of a new subfield in order to explore the possibilities . . .

$$x_F = 2p_{long} / \sqrt{s}$$

Transverse-momentum-dependent distributions and single-spin asymmetries

- 1990: “Sivers mechanism” proposed in attempt to understand observed asymmetries
- Departs from traditional *collinear* factorization assumption in pQCD and proposes correlation between the *intrinsic transverse motion* of the quarks and gluons and the proton’s spin

Sivers distribution: first transverse-momentum-dependent parton distribution function describing a spin-momentum correlation

*New frontier! Parton **dynamics** inside hadrons, and in the hadronization process*

D.W. Sivers
PRD41, 83 (1990)

$$s \cdot (p_1 \times p_2)$$

Spin and momenta of
partons and/or hadrons

Spin-spin and spin-momentum correlations in QCD bound states

Unpolarized

$$f_1 = \text{circle with a dot}$$

Spin-spin correlations

$$g_{1L} = \text{circle with dot and right arrow} - \text{circle with dot and left arrow} \quad \text{Helicity}$$

$$h_{1T} = \text{circle with dot and up arrow} - \text{circle with dot and down arrow} \quad \text{Transversity}$$

Worm-gear
(Kotzinian-Mulders)

$$g_{1T} = \text{circle with dot and right arrow} - \text{circle with dot and left arrow}$$

Spin-momentum correlations

$$S \cdot (p_1 \times p_2)$$

$$f_{1T}^\perp = \text{circle with dot and up arrow} - \text{circle with dot and down arrow} \quad \text{Sivers}$$

$$h_1^\perp = \text{circle with dot and right arrow} - \text{circle with dot and left arrow} \quad \text{Boer-Mulders}$$

$$h_{1L}^\perp = \text{circle with dot and up arrow} - \text{circle with dot and down arrow} \quad \text{Worm-gear} \quad h_{1T}^\perp = \text{circle with dot and right arrow} - \text{circle with dot and left arrow}$$

Pretzelosity

Spin-spin and spin-momentum correlations in QCD bound states

Unpolarized

$$f_1 = \text{[Diagram: circle with a dot in the center]}$$

Spin-spin correlations

$$g_{1L} = \text{[Diagram: two circles with arrows pointing right, separated by a minus sign]} \quad \text{Helicity}$$

Worm-gear
(Kotzinian-Mulders)

$$g_{1T} = \text{[Diagram: two circles with arrows pointing up, separated by a minus sign]} \quad \text{[Image: worm gear]$$

Lots of evidence from deep-inelastic lepton-nucleon scattering experiments over past ~10 years that many of these correlations are nonzero in nature!

Spin-momentum correlations

$$S \cdot (p_1 \times p_2)$$

$$h_1^\perp = \text{[Diagram: two circles with arrows pointing down, separated by a minus sign]} \quad \text{Boer-Mulders}$$

$$h_{1L}^\perp = \text{[Diagram: two circles with arrows pointing right, separated by a minus sign]} \quad \text{Worm-gear} \quad h_{1T}^\perp = \text{[Diagram: two circles with arrows pointing up, separated by a minus sign]} \quad \text{Pretzelosity}$$

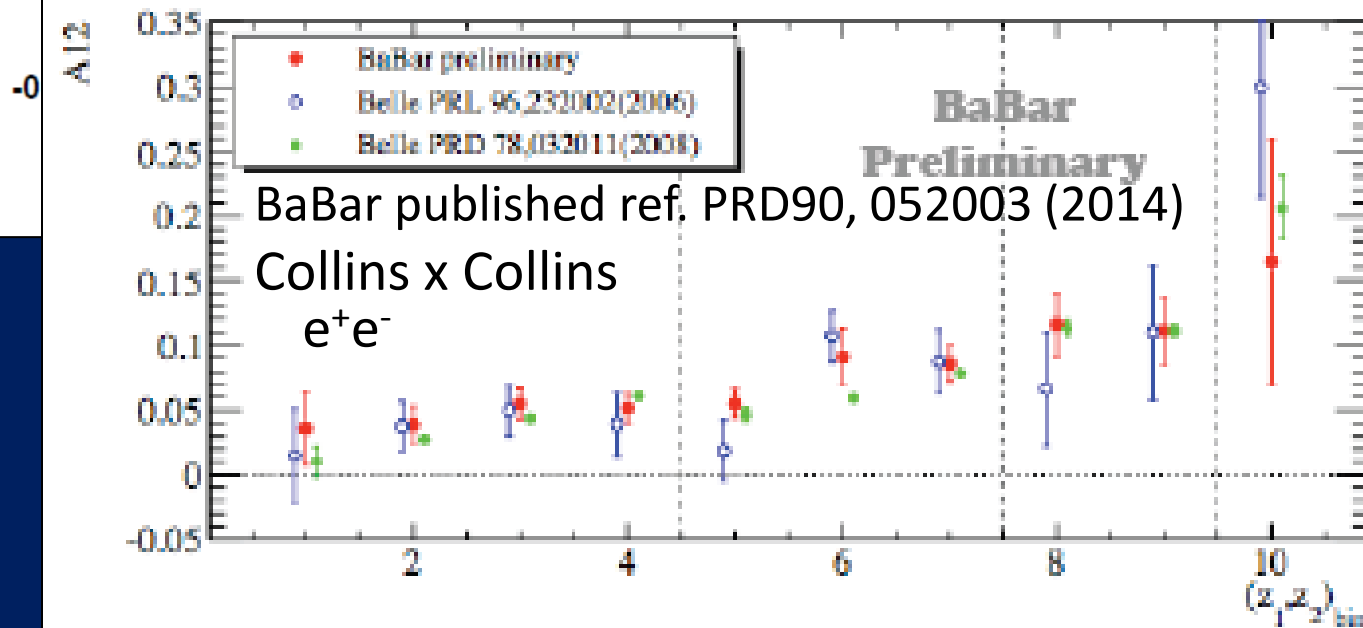

$2 \langle \cos 2\phi \rangle$

$\sqrt{s}=6.6$ GeV

FNAL

$\sqrt{s}=19.4$ GeV

RHIC

$\sqrt{s}=62.4$ GeV

$$x_F = 2p_{long} / \sqrt{s}$$

But what about proton-proton collisions?

ANL

$\sqrt{s}=4.9$ GeV

BNL

$\sqrt{s}=6.6$ GeV

FNAL

$\sqrt{s}=19.4$ GeV

RHIC

$\sqrt{s}=62.4$ GeV

Strikingly similar effects across energies!

→ Continuum between nonperturbative/nonpartonic and perturbative/partonic descriptions of this nonperturbative structure?

Single-spin asymmetries in transversely polarized $p+p$ collisions

- Effects persist to kinematic regimes where perturbative QCD techniques clearly apply
- $p_T = 7$ GeV
 $\rightarrow Q^2 \sim 49$ GeV²!

$p+p \rightarrow \text{hadron} + X$:
Challenging to interpret

- Always huge effects!
- But in $p+p \rightarrow \text{pion} + X$ don't have enough information to separate initial-state (proton structure) from final-state (hadronization) effects

Properties of naive-T-odd spin-momentum correlation functions

- Sivers transverse-momentum-dependent parton distribution function is odd under “naïve-time-reversal” (actually a PT transformation)
 - As is Boer-Mulders spin-momentum correlation
- In 1993, after original 1990 paper by D.W. Sivers, J.C. Collins claimed such functions must vanish
- Only realized in 2002 by Brodsky, Hwang, and Schmidt that could be nonvanishing if *phase interference effects due to color interactions* present

Modified universality of certain transverse-momentum-dependent distributions: *Color in action!*

Deep-inelastic lepton-nucleon
scattering:

Attractive final-state interactions

Quark-antiquark annihilation to
leptons:

Repulsive initial-state interactions

As a result, get *opposite sign* for the Sivers transverse-momentum-dependent pdf when measure in semi-inclusive DIS versus Drell-Yan: *process-dependent* pdf! (Collins 2002)

Modified universality of certain transverse-momentum-dependent distributions: *Color in action!*

Deep-inelastic lepton-nucleon scattering:

Attractive final-state interactions

Quark-antiquark annihilation to leptons:

Repulsive initial-state interactions

Still waiting for a polarized quark-antiquark annihilation measurement to compare to existing lepton-nucleon scattering measurements . . .

Modified universality requires full QCD: Gauge-invariant quantum field theory

We have ignored here the subtleties needed to make this a gauge invariant definition: an appropriate path ordered exponential of the gluon field is needed [18].

1993 claim by J.C. Collins that such processes must vanish

gauge links have physical consequences;
quark models for non vanishing Sivvers function,

SIDIS final state interactions

Brodsky, Hwang, Schmidt, PL B530 (2002) 99 - Collins, PL B536 (2002) 43

An earlier proof that the Sivvers asymmetry vanishes because of time-reversal invariance is invalidated by the path-ordered exponential of the gluon field in the operator definition of parton densities. Instead, the time-reversal argument shows that the Sivvers asymmetry is reversed in sign in hadron-induced hard processes (e.g., Drell-Yan), thereby violating naive universality of parton densities. Previous phenomenology with time-reversal-odd parton densities is therefore validated.

$$[f_{1T}^{q\perp}]_{\text{SIDIS}} = -[f_{1T}^{q\perp}]_{\text{DY}}$$

Slide from M. Anselmino, Transversity 2014

Physical consequences of a gauge-invariant quantum theory: Aharonov-Bohm (1959)

Wikipedia:

“The Aharonov–Bohm effect is important conceptually because it bears on three issues apparent in the recasting of (Maxwell's) classical electromagnetic theory as a gauge theory, which before the advent of quantum mechanics could be argued to be a mathematical reformulation with no physical consequences. The Aharonov–Bohm thought experiments and their experimental realization imply that the issues were not just philosophical.

The three issues are:

- whether potentials are "physical" or just a convenient tool for calculating force fields;
- whether action principles are fundamental;
- the principle of locality.”

Physical consequences of a gauge-invariant quantum theory: Aharonov-Bohm (1959)

Physics Today, September 2009 :

The Aharonov–Bohm effects: Variations on a subtle theme,
by Herman Batelaan and Akira Tonomura.

“Aharonov stresses that the arguments that led to the prediction of the various electromagnetic AB effects apply equally well to any other gauge-invariant quantum theory. In the standard model of particle physics, the strong and weak nuclear interactions are also described by gauge-invariant theories. So one may expect that particle-physics experimenters will be looking for new AB effects in new domains.”

Physical consequences of a gauge-invariant quantum theory: Aharonov-Bohm effect in QCD!!

*Simplicity of these two processes:
Abelian vs. non-Abelian nature of the gauge
group doesn't play a major qualitative role.*

*BUT: In QCD expect additional, new effects
due to specific non-Abelian nature of the
gauge group*

See e.g. Pijlman, hep-ph/0604226
or Sivers, arXiv:1109.2521

QCD Aharonov-Bohm effect:

Color entanglement

- 2010: Rogers and Mulders predict *color entanglement* in processes involving $p+p$ production of hadrons if quark transverse momentum taken into account
- Quarks become correlated *across* the two protons
- Consequence of QCD specifically as a *non-Abelian* gauge theory!

$$p + p \rightarrow h_1 + h_2 + X$$

Color flow can't be described as flow in the two gluons separately. Requires simultaneous presence of both.

Huge transverse spin asymmetries in $p+p$ a color entanglement effect??

Testing the Aharonov-Bohm effect in QCD as a non-Abelian gauge theory

- Look for contradiction with predictions for the case of *no* color entanglement
- But first need to parameterize (unpolarized) transverse-momentum-dependent pdfs from world data
 - Can put better constraints on unpolarized predictions because of more available data

Testing the Aharonov-Bohm effect in QCD as a non-Abelian gauge theory

Get predictions from fits to data where no entanglement expected

$p+A \rightarrow \mu^+ + \mu^- + X$
for different
invariant masses:
No color
entanglement
expected

Testing the Aharonov-Bohm effect in QCD as a non-Abelian gauge theory

Get predictions from fits to data where no entanglement expected

Make predictions for processes where entanglement is expected; look for deviation

Summary

- Early years of rewarding new era of quantitative basic research in QCD!
- Gradually shifting to think about QCD systems in new ways, focusing on topics/ideas/concepts that have long been familiar to the world of condensed matter physics
 - All sorts of correlations within systems
 - Quantum mechanical phase interference effects
 - Quantum entangled systems
- Will be exciting to continue testing and exploring these ideas and phenomena in upcoming years . . .

Hadronization

- Not as far along as nucleon structure—less of a focus in earlier years
- Recent advances via
 - TMD FFs
 - Collinear twist-3 functions to describe hadronization
 - Dihadron (interference) FF
 - Hadronization from nuclei

Related talks by M. Radici, A. Kotzinian, I. Garzia, M. Grosse Perdekamp, F. Giordano, M. Contalbrigo, Y. Guan, O. Eyser, A. Vossen, + other p+p talks and all SIDIS talks . . .

Deep-inelastic lepton-nucleon scattering: A tool of the trade

- Probe nucleon with an electron or muon beam
- Interacts electromagnetically with (charged) quarks and antiquarks
- “Clean” process theoretically—quantum electrodynamics well understood and easy to calculate!

Parton distribution functions inside a nucleon: The language we've developed (so far!)

What momentum fraction would the scattering particle carry if the proton were made of ...

Decades of deep-inelastic lepton-nucleon scattering data: What have we learned?

$$\frac{d^2\sigma^{ep\rightarrow eX}}{dx dQ^2} = \frac{4\pi\alpha_{e.m.}^2}{xQ^4} \left[\left(1 - y + \frac{y^2}{2} \right) F_2(x, Q^2) - \frac{y^2}{2} F_L(x, Q^2) \right]$$

- Wealth of data largely thanks to proton-electron collider, HERA, in Hamburg, which run 1992-2007
- Rich structure at low x
- Half proton's linear momentum carried by gluons!

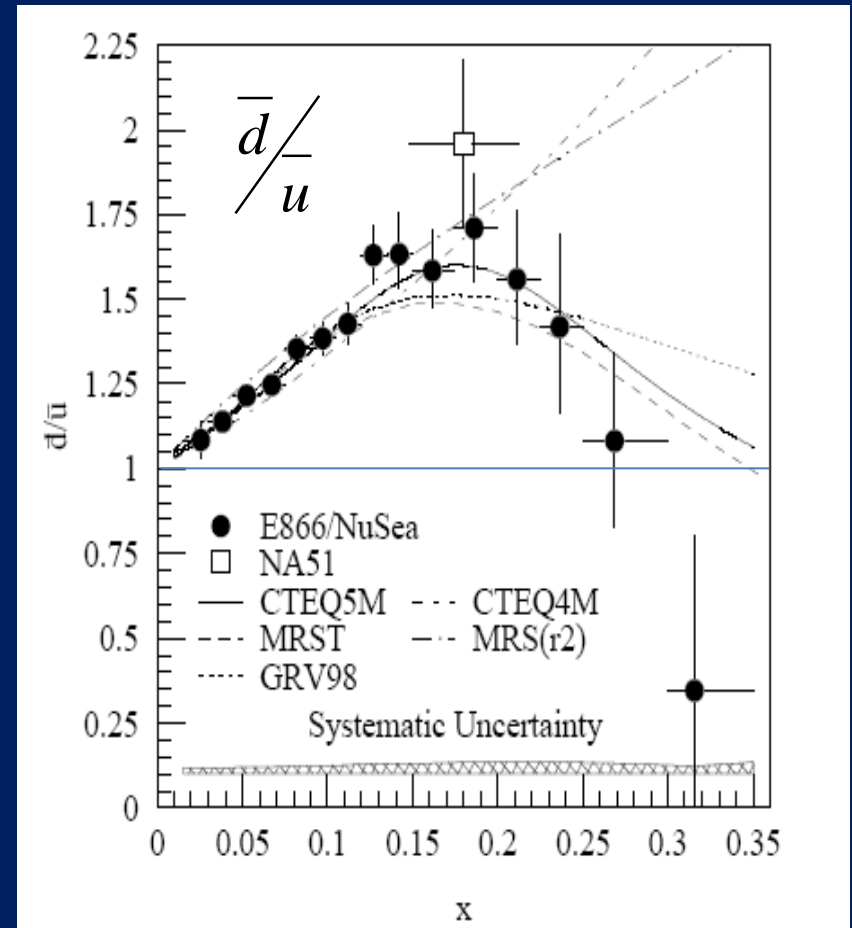

Partonic structure of the nucleon

- Probing the proton at different energy scales offers information on different aspects of partonic structure

And a (relatively) recent surprise from p +hydrogen, p +deuterium collisions

- Fermilab Experiment 866 used proton-hydrogen and proton-deuterium collisions to probe nucleon structure via the Drell-Yan process
$$q + \bar{q} \rightarrow \mu^+ + \mu^-$$
- Would expect anti-up/anti-down ratio of 1 if sea quarks are only generated dynamically by gluon splitting into quark-antiquark pairs
- Measured flavor asymmetry in the quark sea, with striking x behavior
- Indicates some kind of “primordial” sea quarks!

PRD64, 052002 (2001)

And a (relatively) recent surprise from p +hydrogen, p +deuterium collisions

- Fermilab Experiment 866 used proton-hydrogen and proton-deuterium collisions to probe nucleon structure via the Drell-Yan process

- *Hadronic collisions play a complementary role to electron-nucleon scattering and have let us continue to find surprises in the rich linear momentum structure of the proton, even after > 40 years!*
- Measured flavor asymmetry in the quark sea, with striking x behavior
- Indicates some kind of “primordial” sea quarks!

PRD64, 052002 (2001)

Complementarity of Drell-Yan and DIS

DIS

Drell-Yan

- Both deep-inelastic lepton-nucleon scattering (DIS) and quark-antiquark annihilation to leptons (Drell-Yan process) are tools to probe the quark and antiquark structure of hadrons

Perturbative QCD

- Take advantage of running of the strong coupling constant with energy (*asymptotic freedom*)—weak coupling at high energies (short distances)
- Perturbative expansion as in quantum electrodynamics (but many more diagrams due to gluon self-coupling!!)

Perturbative QCD

- Take advantage of running of the strong coupling constant

Most importantly: Perturbative QCD provides a rigorous way of relating the fundamental field theory to a variety of physical observables!

- Perturbative QCD is a quantum electrodynamics (but many more diagrams due to gluon self-coupling!!)

Parton distribution functions in perturbative QCD calculations of observables

$$\sigma(pp \rightarrow \pi^0 X) \propto \underline{q(x_1)} \otimes \underline{g(x_2)} \otimes \underline{\hat{\sigma}^{qg \rightarrow qg}(\hat{s})} \otimes \underline{D_q^{\pi^0}(z)}$$

High-energy processes have predictable rates given:

- Partonic hard scattering rates (calculable in pQCD)
- Parton distribution functions (experiment or lattice)
- Fragmentation functions (experiment or lattice)

} Universal non-perturbative factors

Spin-spin and spin-momentum correlations in QCD bound states

U = unpolarized L = longitudinally polarized T = transversely polarized
N = nucleon q = quark

N \ q			
	U	L	T
U	f_1		h_1^\perp
L		g_1	h_{1L}^\perp
T	f_{1T}^\perp	g_{1T}^\perp	$h_1 h_{1T}^\perp$

High-energy QCD: Thinking in terms of individual partons

- Pdfs are *single-parton* functions in *single* nucleons
 - Or in nuclei, but typically still think of partons in individual nucleons within nucleus
- Can we go beyond this single-parton picture while staying in the hard (short-distance) limit of perturbative QCD?

An alternative approach to describing the large single-spin asymmetries:

Higher-twist multiparton correlations

- Extend our ideas about (single-parton) pdfs to correlation functions that can't be associated with a single parton
- Non-perturbative structure \rightarrow matrix elements involving the quantum mechanical *interference* between scattering off of a (quark+gluon) and scattering off of a single quark (of the same flavor and at the same x)
 - Can also have interference between (gluon+gluon) and single gluon
 - No explicit dependence on partonic transverse momentum
 - Efremov+Teryaev 1981, 84; Qiu+Sterman 1991, 98

Beware: Two common usages of the term “twist”

- Formal definition of twist: “mass dimension minus spin” of the operator in a matrix element within the Operator Product Expansion
 - “Leading twist” is twist-2
 - Twist- n *matrix element* carries a factor of $1/Q^{(n-2)}$
- But – *observables* with measurable contributions from terms suppressed by a factor of $1/Q^{(n-2)}$ often referred to as sensitive to “twist- n ” contributions
 - Never measure a matrix element, only matrix elements squared!
 - To get $1/Q$ term describing an *observable*, need interference term in the square modulus:
 - $A = \text{order } 1 + \text{order } 1/Q + \text{order } 1/Q^2 + \dots$
 - $|A|^2 = |\text{order } 1|^2 + |\text{order } 1/Q|^2 + (\text{order } 1)(\text{order } 1/Q)^* + (\text{order } 1)^*(\text{order } 1/Q) + \dots$
 - So twist-3 term in matrix element times *twist-2* term gives $1/Q$
 - Square modulus of *twist-3* term gives $1/Q^2$, sometimes referred to as “twist-4”

Transverse single-spin asymmetries provide new information on hadron structure

- Leading contribution to transverse single-spin asymmetries comes from *either*:
 - Convolution of two twist-2 *transverse-momentum-dependent* parton distribution functions and/or fragmentation functions, or . . .
 - Convolution of one twist-2 collinear pdf or fragmentation function and one twist-3 (collinear) *multiparton correlation* matrix element

Multiparton correlations in hadronization

- Traditional fragmentation functions describe probability of single parton to hadronize into particular hadron, as function of momentum fraction (z) of parton carried by the final hadron
- Can have matrix elements describing *multiparton correlations in hadronization*
 - Interference between a (quark+gluon) hadronizing and only a quark
 - Similarly, interference between (gluon+gluon) and only a single gluon
 - Kanazawa+Koike, 2000

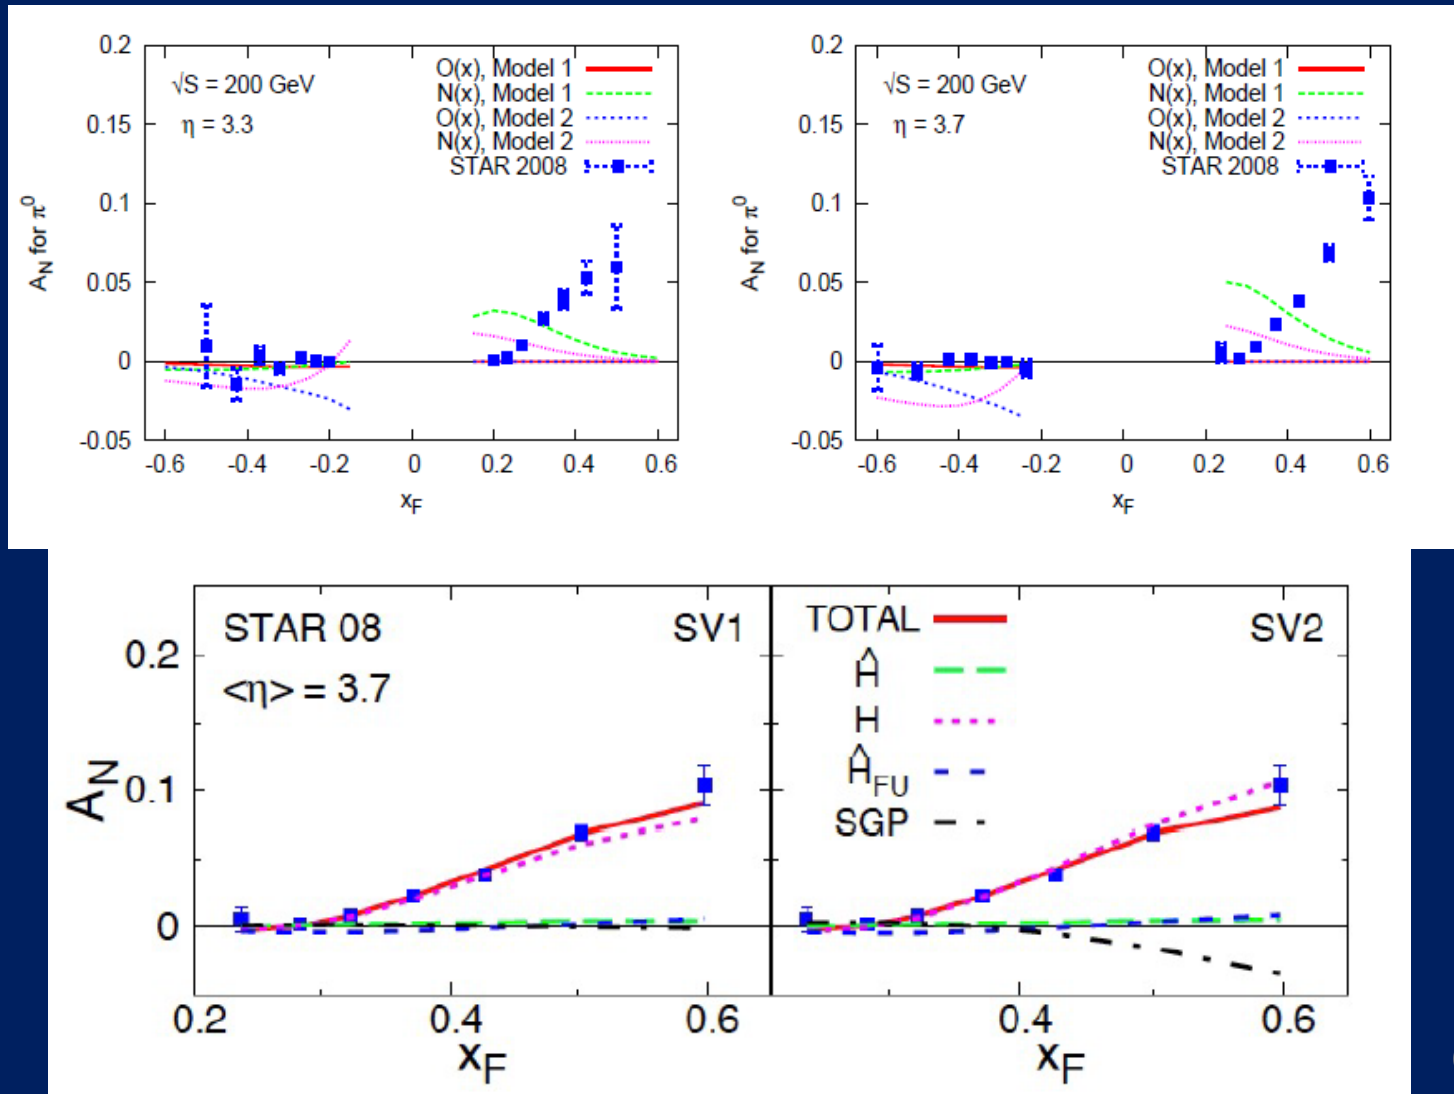

Transverse-momentum-dependent functions and twist-3 multiparton correlators

- Twist-3 (collinear) multiparton correlators believed to be related to k_T -moments of (twist-2)TMD pdfs and fragmentation functions
 - NPB667, 201 (2003); PRL97, 082002 (2006)
- To directly constrain TMD functions with experimental data, need *two* scales
 - Hard momentum
 - Observable sensitive to parton intrinsic momentum
 - Note: Original hadronic asymmetries only measured a single scale

Twist-3 multiparton correlations to interpret inclusive A_N data from RHIC

Making progress!

Inclusive hadron A_N in $e+p$

Phenomenology: twist-3

Gamberg, Kang, Metz, Pitonyak, AP (to appear)

$\hat{H}_{FU}^{h/q} = 0$. allows for a comparison with TMD results directly

Collins contribution is not suppressed, Sivers dominates. $\pi^+\pi^-$ similar to TMD

Magnetic and electric A-B effects; Type-I and Type-II A-B effects

Box 1. Types and duals

Physics Today, September 2009

The original magnetic and electric Aharonov–Bohm effects (panels a and b) are type I effects in the sense that in an ideal experiment, the electron sees no \mathbf{B} or \mathbf{E} fields, though it does traverse different potentials \mathbf{A} and V . In their respective dual effects—the Aharonov–Casher effect (panel c) and the so-called neutron-scalar AB effect (panel d)—polarized neutrons (neutral particles with magnetic dipole moments) replace unpolarized electrons, and electrostatic configurations change places with solenoids.¹⁰ In panel c, a neutron interferometer encloses a line of charge, and in panel d, neutrons pass through pulsed solenoids. These duals are classified as type II effects because the neutron must traverse a nonvanishing \mathbf{E} or \mathbf{B} field.

In either case, to acquire an AB phase shift, the electron or neutron must pass through a region of nonzero electromagnetic potential. That quantum mechanical result seems to elevate the status of the potentials to a physical reality absent from classical electromagnetism. Yakir Aharonov has pointed out that the potentials do overdetermine the experimental outcome; the phase shift need only be known modulo 2π . An alternative view is that the original magnetic AB effect shows electromagnetic fields acting nonlocally.¹

For type II effects, the wavepackets can plow straight through force fields, and forces are allowed in the interaction. But the AB interpretation requires

that the emerging wavepackets not be deflected or delayed in any way. Quantum mechanical descriptions generally circumvent the notion of forces. But one can use here an operational definition of forces that might be mimicking an AB effect: If the interaction has produced no deflection or delay, there were no forces.

Slide from P. Mulders

$$\psi' = P e^{ie \int ds \cdot A} \psi$$

$$\psi_i(x) |P\rangle = P e^{-ig \int_x^{x'} ds_\mu A^\mu} \psi_i(x') |P\rangle$$
