# Assumptions of physics: project overview 

Christine A. Aidala (caidala@umich.edu) Gabriele Carcassi (carcassi@umich.edu)

Department of Physics - University of Michigan

## Typical view in the foundations of physics

- Start with the theory that describes "what really happens"
- With the most complicated and most complete description
- Gradually derive other theories as approximations

The Assumptions of Physics project does not proceed in this manner
approximation

## Understanding fundamental structures

Even probability spaces
are not fundamental structures

I.e. Before saying "there is a $50 \%$ chance to get tails" we need to define what tails, chance and $50 \%$ mean

- What are the "correct" axioms and definitions on which to build scientific theories? How can they be justified?

## Physical theories

Specializations of the general theory under the different assumptions

## Assumptions

## General theory

Basic requirements and definitions valid in all theories

## States and processes

## Informational granularity

Experimental verifiability

## Assumptions of Physics

## - Objectives:

- Develop a mathematical framework that can serve as the foundation for all scientific theories (i.e. a mathematical theory about scientific theories)
- Start from physical principles and assumptions and derive the math (not start from the math and add the physics later through an "interpretation")
- Each mathematical object must have a clear physical meaning (no object is unphysical, can read math proofs as logical arguments on the physics)
- Construct concepts and tools that span different disciplines (nature does not care about divisions in fields of knowledge)
- Explore what happens when the assumptions fail, possibly leading to new physics ideas

## The logic of experimental verifiability

Science deals with well-posed sets of assertions (non-contradictory) that have a single truth value (universal) that can be defined/ascertained experimentally (evidence based)
$\Rightarrow$ Verifiable statements: assertions that can be experimentally verified in a finite time

Examples:
The mass of the photon is less than $10^{-13} \mathrm{eV}$ If the height of the mercury column is between 24 and 25 millimeters then its temperature is between 24 and 25 Celsius
If I take $2 \pm 0.01 \mathrm{Kg}$ of Sodium- 24 and wait $15 \pm 0.01$ hours there will be only $1 \pm 0.01 \mathrm{Kg}$ left

Counterexamples:
Chocolate tastes good (not universal)
It is immoral to kill one person to save ten (not universal and/or evidence-based)
The number 4 is prime (not evidence-based)
This statement is false (not non-contradictory)
The mass of the photon is exactly 0 eV (not verifiable due to infinite precision)

We have to keep in mind that the meaning of the statements, their relationships and what truth values are allowed depends on context (e.g. premise, theory, etc...)

The mass of the electron is $511 \pm 0.5 \mathrm{KeV}$

When measuring the mass, it is a verifiable hypothesis
When performing particle identification, it is assumed to be true

## Axioms of logic

Axiom 1.2 (Axiom of context). A statements is an assertion that is either true or false. A logical context $\mathcal{S}$ is a collection of statements with well defined logical relationships. Formally, a logical context $\mathcal{S}$ is a collection of elements called statements upon which is defined a function truth : $\mathcal{S} \rightarrow \mathbb{B}$.

Axiom 1.4 (Axiom of possibility). A possible assignment for a logical context $\mathcal{S}$ is a map $a: \mathcal{S} \rightarrow \mathbb{B}$ that assigns a truth value to each statement in a way consistent with the content of the statements. Formally, each logical context comes equipped with a set $\mathcal{A}_{\mathcal{S}} \subseteq \mathbb{B}^{\mathcal{S}}$ such that truth $\in \mathcal{A}_{\mathcal{S}} . A$ map $a: \mathcal{S} \rightarrow \mathbb{B}$ is a possible assignment for $\mathcal{S}$ if $a \in \mathcal{A}_{\mathcal{S}}$.

Axiom 1.9 (Axiom of closure). We can always find a statement whose truth value arbitrarily depends on an arbitrary set of statements. Formally, let $S \subseteq \mathcal{S}$ be a set of statements and $f_{\mathbb{B}}: \mathbb{B}^{S} \rightarrow \mathbb{B}$ an arbitrary function from an assignment of $S$ to a truth value. Then we can always find a statement $\overline{\mathrm{s}} \in \mathcal{S}$ that depends on $S$ through $f_{\mathbb{B}}$.

| $S_{1}$ | $S_{2}$ | $S_{3}$ | ... | $f\left(s_{1}, s_{2}, s_{3}\right)$ |
| :---: | :---: | :---: | :---: | :---: |
| T | T | F | ... | T |
| T | F | T | $\ldots$ | T |
| T | F | F | $\cdots$ | F |

## Axioms of verifiability

Axiom 1.27 (Axiom of verifiability). A verifiable statement is a statement that, if true, can be shown to be so experimentally. Formally, each logical context $\mathcal{S}$ contains a set of statements $\mathcal{S}_{v} \subseteq \mathcal{S}$ whose elements are said to be verifiable. Moreover, we have the following properties:

- every certainty $\top \in \mathcal{S}$ is verifiable
- every impossibility $\perp \in \mathcal{S}$ is verifiable
- a statement equivalent to a verifiable statement is verifiable

Remark. The negation or logical NOT of a verifiable statement is not necessarily a verifiable statement.

All tests must succeed

Axiom 1.32 (Axiom of countable disjunction verifiability). The disjunction of a countable collection of verifiable statements is a verifiable statement. Formally, let $\left\{\mathrm{s}_{i}\right\}_{i=1}^{\infty} \subseteq \mathcal{S}_{v}$ be a countable collection of verifiable statements. Then the disjunction $\bigvee_{i=1}^{\infty} \mathrm{s}_{i} \in \mathcal{S}_{v}$ is a verifiable statement.

$s_{1}$ Test Result
T SUCCESS (in finite time) FAILURE (in finite time)
F UNDEFINED

Axiom 1.31 (Axiom of finite conjunction verifiability). The conjunction of a finite collection of verifiable statements is a verifiable statement. Formally, let $\left\{s_{i}\right\}_{i=1}^{n} \subseteq \mathcal{S}_{v}$ be a finite collection of verifiable statements. Then the conjunction $\bigwedge_{i=1}^{n} \mathrm{~s}_{i} \in \mathcal{S}_{v}$ is a verifiable statement.
$\bigvee_{i=1}^{\infty} S_{i}$

One successful test is sufficient

## Properties of the logic system

## Different algebras for the different types of statements

| Operator | Gate | Statement | Verifiable Statement | Decidable Statement |
| :--- | :--- | :--- | :--- | :--- |
| Negation | NOT | allowed | disallowed | allowed |
| Conjunction | AND | arbitrary | finite | finite |
| Disjunction | OR | arbitrary | countable | finite |

Table 1.3: Comparing algebras of statements.

(Different) notions of equivalences

Definition 1.15. Two statements $\mathrm{s}_{1}$ and $\mathrm{s}_{2}$ are equivalent $\mathrm{s}_{1} \equiv \mathrm{~s}_{2}$ if they must be equally true or false simply because of their content. Formally, $\mathrm{s}_{1} \equiv \mathrm{~s}_{2}$ if and only if $a\left(\mathrm{~s}_{1}\right)=a\left(\mathrm{~s}_{2}\right)$ for all possible assignments $a \in \mathcal{A}_{\mathcal{S}}$.

Are the same statement
"This animal is a bird" = "Questo animale e' un uccello"
Always have the same truth $\qquad$ "This animal is a bird" $\equiv$ "This animal has feathers" truth("This animal is a bird") = truth("That animal is a mammal")

Happen to have the same truth

## Experimental domains (scientific models)

Start with a countable set of verifiable statements

Fill in all possible assignments

From them generate all verifiable statements (close under finite AND countable OR)

Generate all meaningful predictions (close under negation as well)

The points of the
space (the
possibilities, the
distinguishable cases)
are not given a priori
but are constructed
from the chosen $\quad \longrightarrow x=\neg e_{1} \wedge e_{2} \wedge \neg e_{3} \wedge \cdots$ verifiable statements

For each possible assignment we have a theoretical statement that is true only in that case. We call these statements possibilities of the domain.

Each column (statement) is also a set of possibilities

$$
s=\bigvee_{x \in U} x
$$

Topologies (needed for manifold/geometr ic spaces) and $\sigma$ algebras (needed for integration and probability spaces) naturally arise from requiring experimental verifiability

## Topologies and $\sigma$-algebras

Finite AND and countable OR become finite intersection and countable union

Negation and countable AND become complement and countable union

| Basis $\mathcal{B}$ |  |  |  | Experimental domain $\mathcal{D}_{X}$ |  |  | Theoretical domain $\overline{\mathcal{D}_{X}}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $e_{1}$ | $e_{2}$ | $e_{3}$ | ... | $s_{1}=e_{1} \vee e_{2}$ | $s_{2}=e_{1} \wedge e_{3}$ | ... | $\overline{s_{1}}=e_{1} \vee \neg e_{2}$ | $\overline{s_{2}}=\neg e_{1}$ | $\ldots$ |
| F | F | F | ... | F | F | ... | T | T | $\cdots$ |
| ... | ... | ... | $\ldots$ | $\ldots$ | ... | ... | ... | ... | $\ldots$ |
| F | T | F | $\ldots$ | T | F | ... | F | T | ... |
| T | T | F | $\ldots$ | T | F | .. | T | F | $\ldots$ |
| ... | ... | ... | $\ldots$ | ... | ... | ... | ... | ... | ... |

The experimental domain $\mathcal{D}_{X}$ induces a topology on the possibilities $X$.

The theoretical domain $\overline{\mathcal{D}_{X}}$ induces a (Borel) $\sigma$-algebra

## Maximum cardinality of distinguishable cases

Set of distinguishable cases

Test results for countable basis
FTFFFTTTFTFTT...
TFFTTFTTFFFTF... FTFFFTTFTFFTF... FTTFTFTTFTFFT...

Correspond to binary expansion
0.0100011101011...
0.1001101100010... 0.0100011010010... 0.0110101101001...

Correspondence to binary sequence
$\xrightarrow{\square}$

- Sets with greater cardinality (e.g. the set of all discontinuous functions from $\mathbb{R}$ to $\mathbb{R}$ ) cannot represent physical objects
- Issues about higher infinities (e.g. large cardinals) are not relevant, but those surrounding the continuum hypothesis may be

## Topologies and $\sigma$-algebras

All definitions and all proofs about these structures have precise physical meaning in this context

| $s_{1}$ | Test Result |  |
| :---: | :--- | :--- |
|  | SUCCESS (in finite time) |  |
|  | UNDEFINED |  |
|  | F | UNDEFINED |
|  | FAILURE (in finite time) |  |

$\operatorname{int}(A)$ corresponds to the verifiable part of a statement
$\partial A$ corresponds to the undecidable part of a statement
$\operatorname{ext}(A)$ corresponds to the falsifiable part of a statement

If $U \subseteq X$ is an open set then " $x$ is in $U$ " is a verifiable statement (e.g. "the mass of the electron is $511 \pm 0.5 \mathrm{KeV}$ ")

If $\mathrm{V} \subseteq X$ is a closed set then " $x$ is in $V$ " is a falsifiable statement (e.g. "the mass of the electron is exactly 511 KeV ")

## Topologies and $\sigma$-algebras each capture part of the formal structure

If $A \subseteq X$ is a Borel set then " $x$ is in A " is a theoretical statement: a test can be created, though we have no guarantee of termination (e.g. "the mass of the electron in KeV is a rational number" is undecidable, the test will never terminate)

## Physical meaning of separation axioms

- All topologies are Kolmogorov (i.e. $T_{0}$ )
- Possibilities are experimentally well-defined i.e. possibilities constructible from a base by countable AND/OR and NOT (singletons in the $\sigma$-algebra)
- The topology is $T_{1}$ if all possibilities are approximately verifiable
- Possibilities are the limit of a sequence of verifiable statements i.e. possibilities are the countable conjunction of verifiable statements
- The topology is Hausdorff (i.e. $T_{2}$ ) if all possibilities are pairwise experimentally distinguishable
- Given two possibilities, we can find a test that confirms one and excludes the other
- i.e. for any $x_{1}, x_{2} \in X$ there is a statement $s \in \overline{\mathcal{D}}_{X}$ such that $x_{1} \leqslant \operatorname{ver}(s)$ and $x_{2} \leqslant \operatorname{fal}(s)$

[^0]
## Examples

## Standard topology on integers

Decidable domain (all statements are decidable)
Discrete topology (every set is clopen); topology and $\sigma$-algebra both coincide with the power set

## Standard topology on the reals

Finite precision measurements (open intervals are verifiable)
Topology generated by open intervals (coincides with order and metric topology); separable, complete, connected (no clopen sets except full and
 empty set); $\sigma$-algebra is the Borel algebra (strict subset of power set)

## Examples

## Does extra-terrestrial life exist?

Semi-decidable question
Topology $\{\varnothing,\{Y\},\{Y, N\}\}$ is strictly $T_{0} ; \sigma$-algebra is the power set

How many leptons (electron-like particles) are there?
(through direct observation)
Can only measure lower bound (e.g. "there are at least $i$ ")
Topology contains empty set and $\{i, i+1, i+2, \ldots\}$ for all $i$; strictly
$T_{0} ; \sigma$-algebra is the power set

## Inference/causal relationships and continuity

An inference relationship is a map $r: \mathcal{D}_{Y} \rightarrow \mathcal{D}_{X}$ such that $r(s) \equiv s$

Two general and important results:
A causal relationship is a map $f: X \rightarrow Y$ such that $x \leqslant f(x)$

1) Two domains admit an inference relationship if and only if they admit a causal relationship
2) The causal relationship must be a continuous map in the natural topology

## Takeaway

- A "science first" formal structure is possible
- Physically meaningful, mathematically precise, philosophically consistent
- Precise science/math dictionary
- "Well-behaved" mathematical objects are really "well-defined" physical objects
- Experimental verifiability is the basis for scientifically well-defined objects
- Topologies and $\sigma$-algebras arise from scientific epistemological requirements, not from ontological features of the universe
- Most other structures used in science (differential geometry, measure theory, probability theory, Lie algebras, ...) are based on topologies and $\sigma$-algebras
- No progress in the foundations of physics is possible without proper understanding of these connections

## The assumptions of classical mechanics

## Assumption of infinitesimal reducibility

The system is reducible to its parts: giving the state of the whole is equivalent to giving the state of the parts. The system can be subdivided indefinitely.

$\mathcal{S}$ is the state of the infinitesimal parts (i.e. particles)

$V$ is a set of possible amounts of materials

## Density over states

The state of the whole is given by a distribution over the state of the infinitesimal parts (i.e. particles)

$$
\rho: \mathcal{S} \rightarrow \mathbb{R}
$$

Density depends on the state; unit is [amount]/[states]

This presents a puzzle:

$$
\rho\left(s\left(\xi^{a}\right)\right)=\rho\left(\xi^{a}\right)
$$

Under a change of variables $\quad \hat{\xi}^{b}=\hat{\xi}^{b}\left(\xi^{a}\right) \quad s\left(\xi^{a}\right)=s\left(\hat{\xi}^{b}\right)$
we have

$$
\rho\left(\xi^{a}\right)=\left|\frac{\partial \xi^{a}}{\partial \hat{\xi}^{b}}\right| \rho\left(\hat{\xi}^{b}\right) \quad \rho\left(s\left(\xi^{a}\right)\right)=\rho\left(s\left(\hat{\xi}^{b}\right)\right)
$$

How can $\rho$ both change as a density and be an invariant?

## Units

- When we write $\int_{U} \rho(s) d \mathcal{S}, \rho$ is expressed in units of [amount]/[states]
- When we write $\int_{U} \rho\left(\xi^{a}\right) d \xi^{n}, \rho$ is expressed in units of [amount]/[ $\left.\xi^{1}\right] \ldots\left[\xi^{n}\right]$
- It seems we need to characterize the role of units
- The units of some variables depend on the units of others
- E.g. the unit for velocity $v=d x / d t$ along a direction $x$ depends on the unit for distance along that direction and time; the unit for entropy $d S=d Q / T$ depends on the unit for energy and temperature
- Within the state variables $\xi^{a}$, we identify the unit variables $q^{i}$ as those that define the unit system
- A change of units $\hat{q}^{j}=\hat{q}^{j}\left(q^{i}\right)$ must induce a unique transformation $\hat{\xi}^{b}=\hat{\xi}^{b}\left(\xi^{a}\right)$ on all variables

## Phase space (symplectic manifold)

- The structure of phase space is exactly what is needed to define invariant densities over particle states

$$
\hat{q}=100 \mathrm{~cm} / \mathrm{mq}
$$

| The product $\Delta q \Delta k$ <br> is invariant | $\Delta k=1 \mathrm{~m}^{-1}$ | 1 | $\Delta \hat{k}=0.01 \mathrm{~cm}^{-1}$ | 1 |
| :--- | :--- | :--- | :--- | :--- |
|  |  | $\Delta q=1 \mathrm{~m}$ |  |  |

- For a single degree of freedom (i.e. one independent unit variable)

$$
d S=\hbar d q d k=\hbar d \hat{q} d \hat{k}
$$

- For $n$ independent degrees of freedom

$$
d S=\hbar^{n} d q^{n} d k_{n}=\hbar^{n} d \hat{q}^{n} d \hat{k}_{n}
$$

- Canonical variables are those that allow us to express density in the correct units over each independent degree of freedom

## Assumption of deterministic and reversible evolution

Given the state of the system at one time, we are able to predict the state at future times (determinism) and reconstruct (reversibility) the state at past times.

## Hamiltonian mechanics for one degree of freedom

Displacement along the trajectory

$$
\vec{S}=\left(\frac{d q}{d t}, \frac{d p}{d t}, \frac{d t}{d t}\right)
$$

Deterministic and reversible:
flux over a closed surface is zero

$$
\begin{aligned}
& \operatorname{div}(\vec{S})=0 \\
& \vec{S}=-\operatorname{curl}(\vec{\theta})
\end{aligned}
$$

Because $\frac{d t}{d t}=1$ we can choose a gauge such that:

$$
\vec{\theta}=(p, 0,-H(q, p))
$$

This recovers Hamilton's equations

$$
\vec{S}=\left(\frac{d q}{d t}, \frac{d p}{d t}, \frac{d t}{d t}\right)=\left(\frac{\partial H}{\partial p},-\frac{\partial H}{\partial q}, 1\right)=-\operatorname{curl}(\vec{\theta})
$$

## Understanding Hamiltonian mechanics

Each mathematical structure is linked to a specific physical requirement

## Possible contributions

## Bare minima

- Project is very interdisciplinary and requires knowledge from different areas of math, physics and engineering
- We want to create a series of short (12-16 pages) articles that give the basic definitions and main results of each field: the bare minimum one needs to know
- E.g. Set theory: https://assumptionsofphysics.org/resources/bareminima/SetTheory.pdf
- Hourly work

## Other small tasks (hourly work)

- There are a number of smaller questions it would be nice to settle
- Is every Heyting algebra embeddable in a Boolean algebra?
- To make sure we are not ruling anything out
- Finalize last few details in our basic structures
- Find the "correct" morphism that gives us the right product, ...
- Study a Gaussian peak under linear Hamiltonian flow
- To generalize the "classical uncertainty relationship"
- Special relativity from densities
- Look for hints of general relativity in the extended phase space
- See if the link between symplectic form, metric and vector potential leads to relationships to the curvature
- Characterize quantum projections as processes with constraints that maximize entropy
- Analyze the relationship between linearity of mixed (classical mixtures) and pure states (quantum superposition) in quantum mechanics
- Can superposition be fully characterized by "aliasing" of mixed states?
- Some of these questions may be already solved in the literature, some may be hard
- Helping to formalize/organize the questions is also useful

## A new foundation for measures and geometry

- We saw that topological and $\sigma$-algebraic structures come from experimental verifiability: how do we recover the rest?
- Note that measures and metrics are used to give a "size" to sets
- In physics, conceptually, we start with the ability to compare sizes (this is bigger than this); we then construct measurement scales to give numerical values
- The idea is to provide a foundation for measure theory and geometry in the same way: we have the lattice of all possible descriptions (our $\sigma$-algebra); we add a preorder that tells us whether one description is "finer" (i.e. more refined) than another; pick a unit and construct a "measure" that respects the order and that is linear under "disjoint addition"
- The goal is to find a set of sufficient physically justifiable conditions for which such measures can be constructed
- For preliminary work, see https://assumptionsofphysics.org/resources/blueprints/InformationGranularity.pdf

## Physical entropy as counting evolutions

- The idea is to define how to "count" (in a measure theoretic sense) the possible evolutions of a system; we define the process entropy as the logarithm of that count
- State entropy becomes the process entropy associated
 to all possible evolutions that "pass" through that state at that time
- Equilibrium states concentrate the evolutions and therefore they maximize the process entropy
- The goal is, with similar considerations, to rederive the basic laws of thermodynamics in the most possible general setting, and recover the standard formula for entropy (i.e. Gibbs, log of count of states, ...) in specific cases
- For preliminary work, see https://assumptionsofphysics.org/resources/blueprints/ProcessEntropy.pdf

## Other bigger tasks

- Find a reformulation of quantum mechanics that fits better in the framework
- Projective spaces? Use mixed states as prime object? Algebraic?
- Find a set of physical motivations to introduce differentiability and differential forms
- General idea is to describe linear quantities associated to k-dimensional submanifolds (rough ideas in Bachelor's thesis https://assumptionsofphysics.org/Thesis-JohnsonDifferentialGeometry.pdf )

## Final thought

Prima dovete capire le cose nel piccolo, e poi generalizzare

First you have to understand the simple case, and then generalize

Se non avete capito nel piccolo, capirete ancora meno quando generalizzate

If you haven't understood the simple case, you will understand even less when you generalize

[^0]:    $s$ Test Result $\quad x_{1} \quad x_{2}$

    T SUCCESS (in finite time)
